1 Chapter

The custom template is a powerful and dangerous tool. It opens up endless export possibilities and just as many ways for things to go wrong.

2 Extra LaTeX packages

Custom templates may need packages that are not part of the base Docker image — here `cancel`. A document declares them in its frontmatter via `nope-tlmgr::`; the export installs missing ones into the Docker image automatically. The demo template loads `cancel` only if it is available, so the box below tells you whether the package made it into the image:

`cancel` is NOT installed — declare it via `nope-tlmgr: [cancel`

in the frontmatter] The template checks for the package with `\IfFileExists` and switches this box between red and green.

To test it yourself:

1. Export this note once — the box is red: `cancel` is **not** installed.
2. Add `nope-tlmgr: [cancel]` to this note's frontmatter.
3. Export again — the package is installed during the export and the box turns green.

The `IfFileExists` dance is only for this red/green demo. A real template just declares `nope-tlmgr:` in the document (or branding note) and uses plain `\usepackage{...}` — if a package is missing anyway, the export fails and the reason lands in the LaTeX log (keep intermediates via settings to inspect it).
